

Watch While You Eat

Key Performance Indicator Report: Initial Submission

Dhawal P Gargi Saini Anukriti Gongle

1. Introduction

1.1 Problem statement

Young Netflix viewers aged 18 to 30 spend so much time deciding what to watch during a meal, whether on their phone, laptop or television, that they often give up before hitting play. They lose the one window they had to relax and watch, and the platform loses engagement and retention across those users.

1.2 Scope of this report

Each indicator reported below is tied to a specific claim from the validation plan, and is stated together with the formula used and the value computed from the survey export. Problem indicators are drawn from the pre-visit survey. Solution indicators are drawn from the post-visit survey, completed after the respondent had used the high-fidelity prototype. Reversal indicators are computed on the matched pre-to-post pairs. Every figure was recomputed from the raw file and cross-checked against the Tableau workbook and the Python reference calculation; the two agree in all cases.

1.3 Evidence base

Sixty-seven pre-survey responses were submitted, of which 55 passed the screener. Thirty-four of those 55 went on to complete the post-survey, a completion rate of 61.8 per cent. The two sheets are joined on session identifier, and respondents who were screened out are excluded from every denominator. Interactive versions of the views in Appendix A are held in the Tableau Public workbook *WWYE Pre-Post Survey Analysis*.

2. Problem Validation

Table 1. Problem-validation indicators, pre-visit survey, n = 55.

Indicator	Definition	Value	Interpretation
C1. Occasion frequency	Share watching at a meal three or more times a week	85.5%	47 of 55. The occasion is frequent rather than occasional.
C2. Cost of the window	Mean response to how much of the meal was already over, scale 0 to 10	3.2	Deciding consumes roughly a third of the meal. 56% spent over three minutes deciding.
C3. Abandonment, breadth	Share who gave up at least once in the previous month	78.2%	43 of 55. Only 12 respondents never gave up.
C3. Abandonment, intensity	Share answering often or almost every time	10.9%	6 of 55. Chronic abandonment is genuine but narrow.
C3. Falsifier	Share who already know what they want before sitting down	38.2%	21 of 55. The problem does not apply to this group, and holds for the remaining 62%.
C4. Off-platform leak	Share who left the platform when deciding dragged, whether to YouTube, social media or another app	52.7%	29 of 55, of which YouTube accounts for 22. This is the commercially relevant loss.
C5. Severity	Mean reported annoyance of the decision step, scale 0 to 10	5.6	Median 6. Forty-four per cent rate it 7 or higher, indicating a heavy tail.

2.1 Interpretation

The problem is validated on breadth, frequency and off-platform leak, and the result is reported with its limits intact. Chronic abandonment is a minority behaviour at 10.9 per cent, and 38 per cent of respondents do not experience the problem at all. The strongest single result is the off-platform leak: more than half of this audience responds to mealtime choice paralysis by leaving Netflix, and the largest single destination is YouTube.

3. Solution Validation

Table 2. Solution-validation indicators, post-visit survey, n = 34.

Indicator	Definition	Value	Interpretation
Noticed the row	Share answering yes to noticing the new row	79.4%	27 of 34. The shelf is discoverable without prompting.
Perceived speed-up	Share answering faster or much faster than their normal routine	55.9%	19 of 34 faster, 14 the same, 1 slower.
Would have started	Share not answering that they would probably have given up	94.1%	32 of 34, of which 15 would have started easily.

Indicator	Definition	Value	Interpretation
Reduced the struggle	Share answering yes clearly or somewhat	94.1%	32 of 34, although only 6 answered clearly.
Retention on platform	Share answering yes or maybe to staying on Netflix	85.3%	29 of 34. This addresses the C4 leak directly.
Headline desirability	Top box: share rating likelihood to use at 8 or above out of 10	29.4%	10 of 34. Mean 6.0, median 6. The weakest indicator, and the one the decision should rest on.
Guardrail, already-seen	Share reporting the suggestions were content they would already skip	0 of 25	No kill-switch signal. Nine respondents were not shown this question.

3.1 Feature component analysis

Counted across multi-select responses (n = 34), the single best-episode pick per show was cited by 19 respondents, the mood filters by 16, the use of shows already watched by 11, and the jump-to-the-best-moment graph by 3. The components that remove the decision carry the feature. The timeline graph does not justify its build cost at this stage.

4. Before-and-After Reversal

Table 3. Reversal indicators computed on 34 matched pre-to-post pairs.

Indicator	Definition	Value	Interpretation
Reverses C3, abandonment	Share who would have started, among those reporting they give up often	3 of 3	Directionally complete, but far too small a cell to generalise from.
Reverses C4, leak	Share who would remain on the platform, among those reporting an off-platform leak	16 of 18	88.9 per cent. The strongest evidence in the dataset.

4.1 Internal consistency

Mean likelihood to use divides in the direction the hypothesis predicts. Respondents who report having to figure out what to watch rate the feature at 7.1 (n = 9), those who already know rate it at 5.9 (n = 15), and the depends group rates it at 5.1 (n = 10). Reported annoyance and likelihood to use are positively correlated at $r = 0.39$. Demand therefore concentrates in the respondents who carry the problem, which is the pattern a genuine signal produces and a novelty effect would not.

5. Business Case

Following the course formula sheet, retention rate is defined as (customers at end less new customers) divided by customers at start, expressed as a percentage, and customer lifetime value as margin multiplied by $[RR / (1 + \text{discount rate} - RR)]$. The feature is modelled as a retention lift applied to a baseline retention rate. Both the baseline and the lift are assumptions rather than observations, since a single-session fake-door test cannot measure retention. This section therefore frames the scale of the opportunity and does not claim it.

6. Limitations

6.1 Indicators requiring instrumentation

Relative click-through uplift against the in-session baseline, feature adoption, engagement depth measured as dwell, take rate, observed decision latency and funnel conversion all require the interaction event log (row impression, row click and feature dwell), which is not present in the survey export. Year-on-year growth and compound annual growth rate have no time series available, and cannibalisation rate has no control cohort without the feature. These remain the decisive behavioural tests. The survey establishes the problem and stated desirability only.

6.2 Data quality and sampling

The taste-match item is unusable: 30 of 34 responses carry the same value, which is consistent with an untouched default rather than a judgement, and it is therefore not reported. Completer bias should be assumed, since 34 of 55 eligible respondents finished the study and respondents who abandon a survey may plausibly also abandon a prototype, so the reaction figures are likely to skew favourable. The study used a single collection window with no control cohort, and sample sizes are small throughout. The three-respondent reversal cell in Table 3 is indicative only.

7. Conclusion

The problem is validated. The occasion is frequent, abandonment is broad, a majority leak off-platform, and the falsifier has been reported rather than suppressed. The solution is directionally supported but not yet validated. Reaction measures are strongly positive, with 94 per cent reporting they would have started watching and 85 per cent reporting they would remain on the platform, but the single measure that requires the respondent to commit, top-box likelihood to use, stands at 29.4 per cent, and 14 of 34 respondents found the row no faster than their existing routine. The go-or-no-go decision should rest on the behavioural indicators listed in Section 6.1 rather than on the stated measures reported here.

Appendix A. Survey Analysis Views

The views below were built in Tableau Public, in the workbook *WWYE Pre-Post Survey Analysis*, on the joined pre-and-post extract with the eligibility filter applied to every sheet. They are reproduced here at print resolution from the same underlying data. In each panel the darker shading marks the series the chart concerns and the lighter shading provides context.

Figure 1. Survey analysis views. (a) Recruitment funnel, from 67 submissions to 55 eligible respondents to 34 completions. (b) Distribution of likelihood to use at the next meal, with the top box of 8 to 10 shaded dark. (c) Reported action when deciding dragged, with off-platform destinations shaded dark. (d) The falsifier split. (e) Perceived speed against the respondent's normal routine. (f) Feature components rated useful.
